

### **How does CCG work in overview?**

Each licensed dispensary growth location may opt to use the native IndicaGeneSeed and SativaGeneSeed tokens with new token contracts deployed, or may opt for customized token contracts to be deployed for ledgering the plants genetic makeups of Indica/Sativa percentage factors.

These genetic tokens are then utilized within the CCG DApp ecosystem to trigger the growth room contract to batch in what real world plants are currently being grown from seed to harvest, along with how many of each different plant is currently in various stages of growth cycle.

A GrowthXP token contract is also deployed as utility to balance the growth progress of each real world plant in case a plants growth cycle will be completed sooner than expected. These GrowthXP tokens once used in the CCG DApp grow room ecosystem will deplete the growth timer as much time for reduction as needed to bring the plant ledger into a harvestable stage for completion and on-chain ledgering of all such events.
